GCE Chemistry 6CH05 01

Edexcel and BTEC Qualifications

Edexcel and BTEC qualifications come from Pearson, the world's leading learning company. We provide a wide range of qualifications including academic, vocational, occupational and specific programmes for employers. For further information, please call our GCE line on 0844 576 0025, our GCSE team on 0844 576 0027, or visit our qualifications website at www.edexcel.com. For information about our BTEC qualifications, please call 0844 576 0026, or visit our website at www.btec.co.uk.

If you have any subject specific questions about this specification that require the help of a subject specialist, you may find our Ask The Expert email service helpful.

Ask The Expert can be accessed online at the following link: http://www.edexcel.com/Aboutus/contact-us/

Alternatively, you can speak directly to the subject team at Pearson about Edexcel qualifications. Their contact details can be found on this link: www.edexcel.com/teachingservices

Get more from your exam results

...and now your mock results too!

ResultsPlus is Edexcel's free online service giving instant and detailed analysis of your students' exam and mock performance, helping you to help them more effectively.

- See your students' scores for every exam question
- Spot topics, skills and types of question where they need to improve their learning
- Understand how your students' performance compares with Edexcel national averages
- Track progress against target grades and focus revision more effectively with NEW Mock Analysis

For more information on ResultsPlus, or to log in, visit www.edexcel.com/resultsplus. To set up your ResultsPlus account, call 0844 576 0024

Pearson: helping people progress, everywhere

Our aim is to help everyone progress in their lives through education. We believe in every kind of learning, for all kinds of people, wherever they are in the world. We've been involved in education for over 150 years, and by working across 70 countries, in 100 languages, we have built an international reputation for raising achievement through innovation in education. Find out more about how we can help you and your students at: www.pearson.com/uk.

Introduction

The paper was accessible though some questions seemed to challenge many candidates.

Question 21 (a)

Electronic configuration of transition metals was usually well known. Some did not realise the stability of half filled shells, while some thought both elements had five 3d electrons.

21 (a) Chromium is a typical transition metal, although its electronic configuration does **not** fit the general trend found in the first transition series.

Complete the electronic configurations in s,p,d notation for vanadium and chromium.

(1)

Vanadium: [Ar] 152 252 286 382 386 343 452

Chromium: [Ar] 15252pc352 3p53d545

Here the candidate has given the full configurations correctly. This was not penalised but gave them unnecessary work.

Read the question to avoid unnecessary work.

21 (a) Chromium is a typical transition metal, although its electronic configuration does **not** fit the general trend found in the first transition series.

Complete the electronic configurations in s,p,d notation for vanadium and chromium.

(1)

Vanadium: [Ar] 3d.5

Chromium: [Ar] 4s²3d⁴

This is an odd answer, giving a half filled 3d shell for vanadium, but not for chromium.

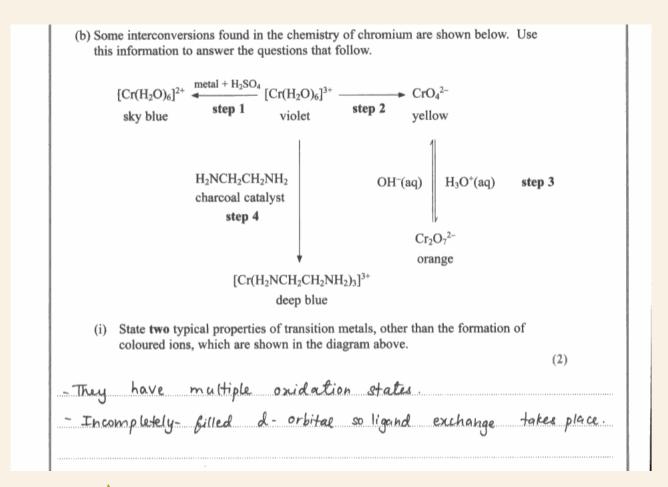

Learn the configuration rules thoroughly, the only variations to the normal shell filling principle are where the atom would be one electron short of a half filled or filled shell.

Question 21 (b) (i)

The key phrase in this question, missed by many candidates is 'in the diagram above'.

As a result catalytic activity and other physical properties were not rewarded.

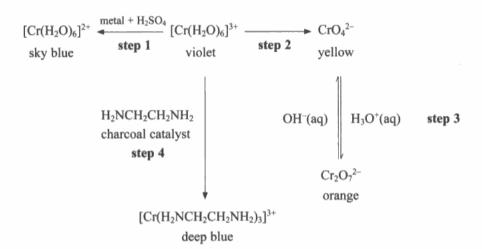

The first point is fine.

The second needs to be expressed as 'complex formation' to gain credit.

Read the question and give the obvious answers.

(b) Some interconversions found in the chemistry of chromium are shown below. Use this information to answer the questions that follow.

(i) State **two** typical properties of transition metals, other than the formation of coloured ions, which are shown in the diagram above.

This is high risk. Three answers are given and **all** must be correct to gain 2 marks. Fortunately catalytic activity was regarded as neutral. They are not all paramagnetic.

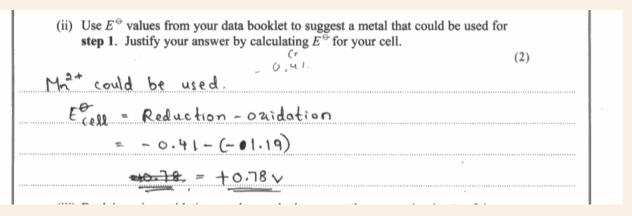

Do not use the scatter gun approach giving several answers in the hope that one or two may be correct.

Question 21 (b) (ii)

The popular choice here was zinc, with a cell value of 0.35 V.

Alkali metals were penalised as they would also react vigorously with water, so only one mark was then available.

There were calculation errors, significant figures lost, and sometimes just a failure to identify the metal despite a correct calculation.

Notice how the ion has been given rather than the metal, which would not work. However, the correct calculation gets one mark.

(ii) Use E^{\oplus} values from your data booklet to suggest a metal that could be used for step 1. Justify your answer by calculating E^{\oplus} for your cell.

E for the cell is -0.41 V. Zn could be used as the metal as it's E is -0.76 V due to the rule of electrons flowing from the more negative to the positive

Zinc has been chosen correctly, but the calculation of E for the cell has not been done.

Check each question has been fully answered before going on to the next.

Question 21 (b) (iii)

The most common error was to say the oxidation number of chromium does not change, without giving the value, +6.

Some answers used incorrect language referring to total oxidation number as -2, which is the algebraic sum of the oxidation numbers or the charge on the ion.

Some thought oxygen changed its oxidation number.

(iii) Explain, using oxidation numbers, whether or not the conversion in step 3 is a redox reaction.

(2)

No. The oxidation number of chrowing in Croff and Croff Locs not change during the reactions, so the reactions are not redox ones.

The conversion has been recognised as not redox because oxidation number has not changed, but actual oxidation numbers have not been calculated.

Give as much relevant information as you can.

Question 21 (b) (iv-v)

Only weak candidates did not realise that bidentate ligands form two bonds per ligand in part (iv).

Many thought hydrazine contained a double bond and/or had only one or no lone pairs of electrons in part (v).

(iv) The organic compound H₂NCH₂CH₂NH₂ that is used in step 4 is
1,2-diaminoethane, often called ethylenediamine.
It is a bidentate ligand. Explain the meaning of this term.

(1)

A ligand which donotes two lone pair of electrons to the central metal

to firm a dativee covalent bond is called a bidentate ligand.

(v) Explain, in terms of its structure, how H₂NCH₂CH₂NH₂ can act as a bidentate ligand whereas H₂NNH₂ cannot.

(2)

H₂NCH₂CH₂NH₂ thas two lone pair of electrons on the ninegen atom when H₂NNH₂ does not have lone pair of electrons of N because of the double bond.

This is quite a common response. Part (iv) is fine, but in part (v) the candidate does not realise that hydrazine has two lone pairs of electrons. In this case they have decided it contains two four valent nitrogens with a double bond.

Remember nitrogen usually forms three bonds.

Question 21 (c) (i)

Very few candidates did not look up and record the values with signs correctly.

(c) The half-equations relating the interconversion of the species Cr²+(aq), Cr³+(aq) and Cr₂O₂²-(aq) are given below.

Half-equation I: Cr³+(aq) + e⁻ → Cr²+(aq)

Half-equation II: Cr₂O₂²-(aq) + 6e⁻ + 14H⁺(aq) → 2Cr³+(aq) + 7H₂O(l)

(i) Use your data booklet to find E⁶ for each of the above half-equations.

(1)

Half-equation I — ○ · 4 | Volts

Half-equation II — ○ · 13 Volts

The wrong value and sign are given here, the value for chromate(VI), not dichromate(VI) has been given.

Check the precise half equation is correct when looking up electrode potentials.

(c) The half-equations relating the interconversion of the species Cr²⁺(aq), Cr³⁺(aq) and $Cr_2O_7^{2-}$ (aq) are given below. Half-equation I: $Cr^{3+}(aq) + e^- \rightarrow Cr^{2+}(aq)$ **Half-equation II:** $Cr_2O_7^{2-}(aq) + 6e^- + 14H^+(aq) \rightarrow 2Cr^{3+}(aq) + 7H_2O(1)$ (i) Use your data booklet to find E^{\oplus} for each of the above half-equations. (1)

-0.91 Half-equation I Volts 1.33 Half-equation II Volts

Entropies, enthalpies, and electrode potentials must have signs even if positive.

Question 21 (c) (ii)

The equation proved testing as it is not the direction followed by the spontaneous reaction.

Even when the correct sequence was given balancing was also challenging.

Handling the redox potentials to get E cell also proved difficult, though the interpretation of the result was straightforward providing the question was read correctly and information about the disproportionation reaction was given.

*(ii) Write the overall equation for the disproportionation of
$$Cr^{3+}$$
 into Cr^{2+} and $Cr_2O_7^{2-}$.

Use the E^{\oplus} values you have obtained in (c)(i) to show whether or not this disproportionation is feasible under standard conditions.

(4)

$$C+\frac{3+}{(a_A)}+\frac{1}{c}=\frac{1}{(a_A)}+\frac{1}{$$

Here the candidate has managed the correct equation with one slip and forgotten that 6 Cr²⁺ ions form. They have then made an arithmetic error, but managed the correct interpretation.

Practise balancing equations for redox reaction using oxidation numbers. Check arithmetic after each step.

The entities in the equation are correct but there is no attempt to balance it. There is an error in the calculation, but the result is correctly interpreted.

Practise balancing equations for redox reaction using oxidation numbers and practice E cell calculations for reactions that are not spontaneous.

Question 22 (a) (i)

This was usually answered successfully. The best method is to divide percentages by the appropriate relative atomic mass. Credit was given for calculating the molar mass and then calculating moles from the percentages.

22 (a) Tiglic acid is a compound that is used as a defensive agent by some beetles.

(i) Tiglic acid contains, by mass, 60% carbon, 8% hydrogen, with the remainder being oxygen. Show that these data are consistent with the formula C₅H₈O₂.

	_ C	4 1	0
mass:	60 %	8 70	32 %
moles:	5	8	$\frac{32}{16} = 2$
mole ratio :	5	: 8:2	, 0

Empirical formula is C5 H802 which is consistent with the formula given.

This candidate has been penalised for failing to show what they are doing to the carbon and hydrogen percentages.

Always show your working clearly.

(1)

22 (a) Tiglic acid is a compound that is used as a defensive agent by some beetles.

(i) Tiglic acid contains, by mass, 60% carbon, 8% hydrogen, with the remainder being oxygen. Show that these data are consistent with the formula C₅H₈O₂.

(1)

$$C = 12 rem$$
 $H = L rem$
 $S \times 12 = 60$
 $O = 16 rem$
 $S \times 1 = 8$
 $2 \times 16 = 32$
 $60 \% 100 = 60 rem$
 $8\% \% 100 = 8 rem$

Okygen is remainder (37 ram)

This is the correct second method.

The method dividing percentages by molar masses is best.

Question 22 (a) (ii)

The test for a carbon-carbon double bond is well known but must be precisely stated, bromine water changes from yellow/brown to colourless.

The most common test given for a carboxylic acid was phosphorus(V) chloride. This is not conclusive as an alcohol gives the same result, so no credit was given. The best test is that a large volume of sodium carbonate solution can be neutralized.

Test for C=	=C Add Brown	ine water.			
411171811111111111111111111111111111111	- Brown se	olution dec		 	***************************
		, ,			

The test for a carbon-carbon double bond is fine. Ester formation requires concentrated sulfuric acid and heat so a mark was lost here.

Always give reaction reagents and conditions in full in this type of question.

(ii) Tiglic acid contains a carbon-carbon double bond and a carboxylic acid group.

Suggest one test for each of these groups in tiglic acid. State what you would do and what you would see as a positive result for the tests.

(4)

Test for C=C Mix with a small quality of browning.

The army (been solution will decolorise as a positive coult.

The test for a carbon-carbon double bond is incomplete. Bromine rather than bromine water is used but the colour change is given. Though sodium hydroxide does neutralize a carboxylic acid, it is not a unique test, so no credit is given.

Learn details of tests for all major functional groups.

Question 22 (b) (i)

The understanding and application of E/Z nomenclature proved challenging. Good candidates got the reasoning mark by discussing priority in terms of atomic numbers.

(b) It is suggested that the structure of tiglic acid is either that of A or B.

CH₃CH₂

H

COOH

A

B

(i) State, with a reason, whether B is the E- or Z- isomer.

B is a on E - 150 mes because the molecules of most importance are not on the Same Side of the double bond.

This is an example of poor language costing a mark. The correct term is attached group or functional group, not molecule.

(b) It is suggested that the structure of tiglic acid is either that of A or B.

CH₃CH₂

H

COOH

A

B

(i) State, with a reason, whether B is the E- or Z- isomer.

(2)

Z Frether as the identical group, CH₃ is at the

same

side.

The most common wrong answer, totally confusing E/Z with cis/trans.

Question 22 (b) (ii-iii)

Common errors were the omission of charges or wrong numbers of hydrogens in the fragment formulae.

					(.	*)
Test for C=	C Add Bromine					
		tion decolour				
				;		
					ž	
		» · · .	: :		ž	

The carbon chain fragment is two hydrogens short.

Check that carbons have sufficient bonds in each formula.

(ii) The mass spectrum of tiglic acid shows two prominent peaks at mass/charge ratios 45 and 55. Write the formulae of the fragments giving rise to each of these peaks. (2) 45 COOH 55 CH3CH2CHCH (iii) Does this data from the mass spectrum alone enable you to decide which of A or **B** is the structure of tiglic acid? Explain your answer. No, we need to see the other peaks. If there are any additional peaks precimple, this , if we know the M peak we could see if the Mr Is the same.

No charges on the ions and no mention of the same peaks.

In mass spectrometers fragments are always positive ions.

Question 22 (c) (i-ii)

There was often a lack of clear reasoning from the tests in (i).

The application of E/Z in (ii) was beyond most candidates.

(c) The position of a C=C double bond in a molecule can be determined by ozonolysis. The compound is reacted with ozone and then dilute acid, two carbonyl compounds being produced as shown below.

Ozonolysis of tiglic acid gives two carbonyl compounds, C and D.

Compound C gives a silver mirror with Tollens' reagent and gives iodoform with iodine in alkali. CHO-E-H

Compound D does not give a silver mirror with Tollens' reagent, but does give iodoform with iodine in alkali.

*(i) From the results of the experiments, deduce the functional groups present in C and D. By considering the two possible structures for tiglic acid, give the structural formulae of C and D.

From the structures you have drawn, state which of the structures A or B could represent tiglic acid.

(6)

Com Compound c should contain an aldehyde group to give results for the Teattion with Tollen's reagent. And there has to be a - CH3 group attached to the carbon at carbonyl carbon atom. Since compound D gives negative forms lodoform with iodine in alkali it should results for the reaction with toller's reagent it should contain a keture with a carbonyl carbon which a - CH3 group is attached. Therefore D should be a ketone.

C- CH3-C-H D- CH3-C-HCH3

should be tiglic acid. Structure

(ii) Explain whether or not these tests show definitely that your answer to (c)(i) represents tiglic acid.

(1)

the structure B cannot produce 2 compounds. (a cand D)

Examiner Comments

Here the excellent reasoning compensates for two errors in formulae.

Always show your reasoning as fully as possible.

(c) The position of a C=C double bond in a molecule can be determined by ozonolysis. The compound is reacted with ozone and then dilute acid, two carbonyl compounds being produced as shown below.

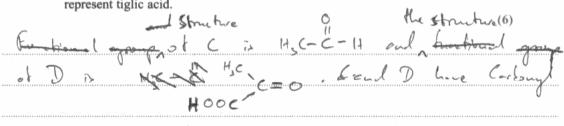

Ozonolysis of tiglic acid gives two carbonyl compounds, C and D.

Compound C gives a silver mirror with Tollens' reagent and gives iodoform with iodine in alkali.

Compound **D** does **not** give a silver mirror with Tollens' reagent, but does give iodoform with iodine in alkali.

*(i) From the results of the experiments, deduce the functional groups present in C and D. By considering the two possible structures for tiglic acid, give the structural formulae of C and D.

From the structures you have drawn, state which of the structures ${\bf A}$ or ${\bf B}$ could represent tiglic acid.

group and the Corboxyliz group as functional groups cospertially.
Standard B regresterts Tight Asid.

(ii) Explain whether or not these tests show definitely that your answer to (c)(i) represents tiglic acid.

Yes then rosults represent Tigliz Axid clepinitely unless no impurities were present.

Though the formulae are correct there is little attempt to reason.

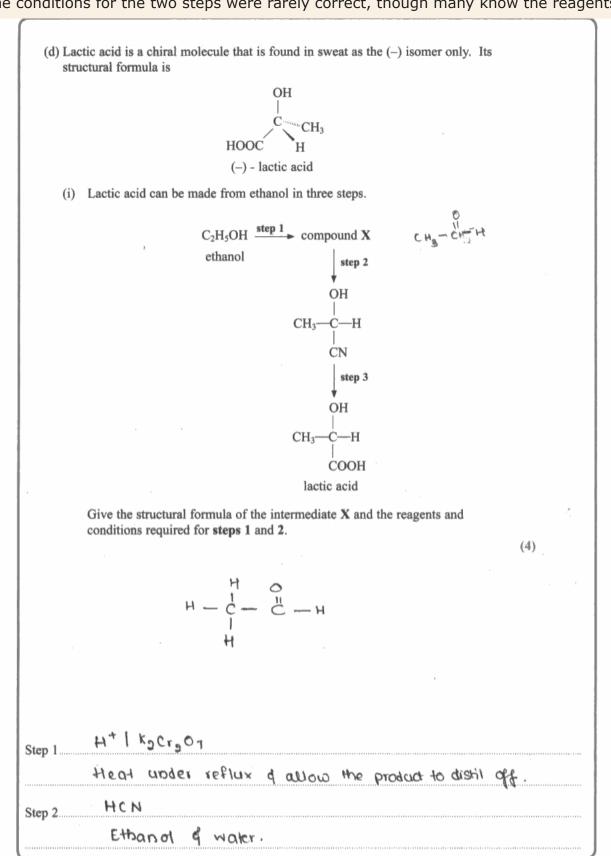

Always show your reasoning as fully as possible.

Question 22 (d) (i)

This question was very challenging.

Quite a few could not give the correct intermediate.

The conditions for the two steps were rarely correct, though many know the reagents.

In step 2 if you reflux first a carboxylic acid forms.

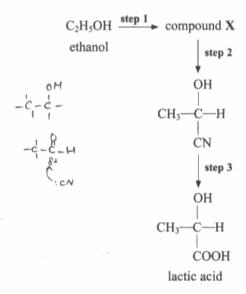

KCN is also needed with HCN.

This type of question requires the candidate to think about the specific experiment in the question and also the way in which the data will be used to calculate the required value. Avoid vague generalisations!

(d) Lactic acid is a chiral molecule that is found in sweat as the (-) isomer only. Its structural formula is

(i) Lactic acid can be made from ethanol in three steps.

Give the structural formula of the intermediate X and the reagents and conditions required for steps 1 and 2.

(4)

Step 1	acioli	fied	potacei um	manganate	(vII)	and	concentrated	H2504.	
	Heat	unde	er reflux.						
Sten 2	HON	with	catalyst	kcN.

KCN needs to be at pH8

Learn chemicals and conditions for organic reactions.

Question 22 (d) (ii)

The most common error was to give nucleophilic substitution.

(ii) Classify the type and mechanism of the reaction that occurs in step 2.

(Field Crops reaction) and nucleophilic addition up necessing carbon dain length.

(ii) Classify the type and mechanism of the reaction that occurs in step 2.

(1)

(ii) Classify the type and mechanism of the reaction that occurs in step 2.

(1)

Nucleophilic substitution.

(ii) Classify the type and mechanism of the reaction that occurs in step 2.

(1)

electrophilic addition

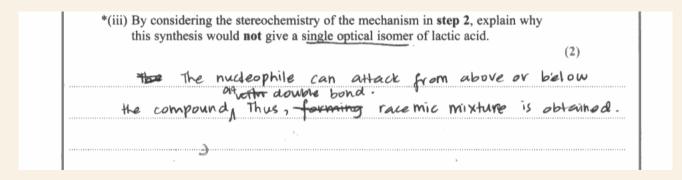

Practise identifying reactions and types.

Question 22 (d) (iii)

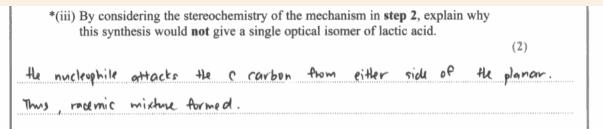

The planarity of ethanal at the carbonyl bond was often missed.

The idea of attack from above or below was usually given but often negated by reference to a carbocation indicating confusion with $S_N 2$.

This scores the mark for attack from above and below but does not mention planarity of the molecule.

This scores the mark for attack from above and below and nearly gains the second mark but the sentence is incomplete. What is planar?

Always check your answers to make sure they make sense.

Question 22 (d) (iv)

There were many ways of gaining this mark. The most common was by responding that the other stereoisomer may be harmful.

(iv) Suggest why synthetic pathways for the manufacture of pharmaceuticals may require reactions that are highly stereospecific.

(1)

Because differences

o in their proprities properties

This is insufficient. If the type of properties such as differences in biochemical properties had been mentioned that would have been fine.

Always be as specific as possible, avoid being vague.

There were many poor answers like this about yield or atom economy.

Many saved the day by giving an example of a dangerous stereoisomer like thalidomide.

Question 23 (a) (iii)

There were many poor responses here. More practice at drawing peptides is needed. It is best to start by learning the displayed peptide link, and then adding the detail. Virtually all combinations of C, N and O were given, with varying numbers of attached hydrogens.

(iii) Draw the structure of the protein chain that would be formed if glycine alone were to be polymerized. Show part of the chain containing two glycine residues.

The peptide bond has an extra hydrogen on the nitrogen, and as this had to be correct to score the second mark, this scores zero.

Practise drawing amides/peptides.

(iii) Draw the structure of the protein chain that would be formed if glycine alone were to be polymerized. Show part of the chain containing two glycine residues.

Two carbons are each bonded to three hydrogens, making them pentavalent.

Check all carbons make four bonds.

(2)

Question 23 (a) (i-ii)

(i) Weaker candidates gave the non-ionic structure. A displayed formula was accepted on this occasion but this might not always be the case.

(ii) Few candidates mentioned the high energy needed to break the bonds and few made bonds between molecules clear. Hydrogen bonding was very commonly given.

23 Proteins are polymers of α -amino acids, the simplest of which is glycine.

(a) (i) Draw the structural formula for the zwitterion of glycine in the solid state.

(1)

(ii) Explain, on the basis of your answer to (a)(i), why glycine has a relatively high melting temperature for such a small molecule.

(2)

The negative charge in the formula is on the wrong oxygen. No mention of ionic attractions between molecules in (ii).

23 Proteins are polymers of α -amino acids, the simplest of which is glycine.

(a) (i) Draw the structural formula for the zwitterion of glycine in the solid state.

(1)

(ii) Explain, on the basis of your answer to (a)(i), why glycine has a relatively high melting temperature for such a small molecule.

(2)

This	15	RIA	use	the	proton	fram	the	Cook	1 9000	P Pro	tonates	Linina
the	W	H2	5000	ip f	oun in	NHz	ov	d (0	0-	thus	He

							V					

The formula is correct and the ionic forces have been recognised, but it is not clear whether the forces are within molecules, or between molecules.

23 Proteins are polymers of α -amino acids, the simplest of which is glycine.

(a) (i) Draw the structural formula for the zwitterion of glycine in the solid state.

(1)

(ii) Explain, on the basis of your answer to (a)(i), why glycine has a relatively high melting temperature for such a small molecule.

(2)

***************************************	It'	has	both	aeldic	and	baric 1	propertie	e and
it co	Ln	form	hydrag	en bo	nd k	petween	two	molecules
of g	lycir	1e		*************************	14461-1717-1817-1847-1847-1947	***********************	************************	***************************************

No mention of ionic attractions between molecules in (ii).

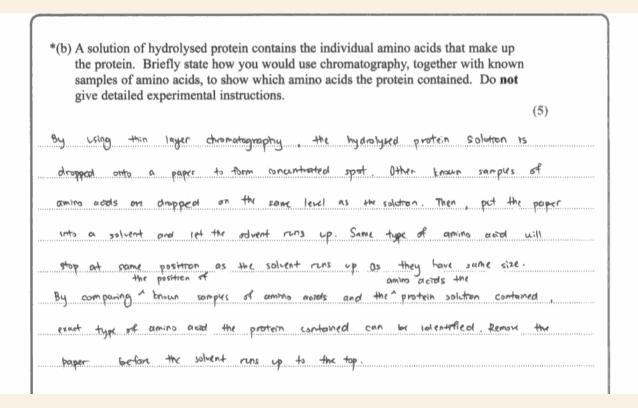

Question 23 (b)

There were various ways of doing this. Most had done thin layer chromatography in one direction, which was fine.

Some described two dimensional chromatography, where different solvents are run at right angles to each other. This was also fine.

Some described column chromatography successfully.

Electrophoresis was not acceptable.

This would have gained full credit if ninhydrin had been mentioned.

It is important to learn details of experiments that you did, and be able to write about them.

*(b) A solution of hydrolysed protein contains the individual amino acids that make up the protein. Briefly state how you would use chromatography, together with known samples of amino acids, to show which amino acids the protein contained. Do not give detailed experimental instructions.

Do the process of Chromatography which gives a coloured spots when sprayed with ninhydrin Record the results with the colour them seen Compare with the data values of known amino acids colour

(5)

the gresult can be considered

This would have scored a second mark if the data compared had been specified as R_f values.

Question 24 (a) (i)

Most realised that it was because the structure of the molecule was not known.

(a) (i) Explain why Perkin's attempted synthesis of quinine was almost certain to fail.

(1)

because he did not know the structure of benzene, hence he would not know how the benzene would react to themical reactions.

A common misconception. Though it is true, it is not enough, to synthesize quinine its full structure needed to be known.

With this type of question it is important to read the passage carefully - the answer was clearly there.

Question 24 (a) (ii)

Very few candidates gained credit here. Most thought that India and/or Holland became more affluent, without considering the reasons.

(ii) Suggest the effect that the growth of the organic chemicals industry in the late
19th century had on Holland and India in particular.

(2)

Synthetic dyer wore made available in large quantities.

and it was cheaper source than using plants.

This gains the first mark for cheaper sources available but only answers part of the question. It does not address its effect on the farmers in India and Holland.

Read the passage carefully, then consider its implications when asked.

(ii) Suggest the effect that the growth of the organic chemicals industry in the late 19th century had on Holland and India in particular.

(2)

This would have increased the export from both

India and Holland and would have increased

the economical growth. The economy in India

would have grown.

This fails to address either marking point. There is no mention of cheaper alternatives and the effect on growers is ignored.

Question 24 (b) (i)

It was important to read that an observation, something you would see, was needed. Then it was necessary to see the significance of this for the proposed structure.

(b) (i) What observation did Kekulé make to show that benzene does **not** react with bromine water? Explain the significance of this with reference to his representation of the molecule.

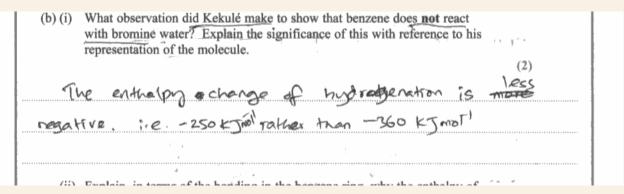

(2)

Benzene didn't decolourke bronne water

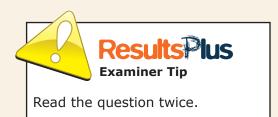

The second part of the question has not been answered.

The key words 'What observation...' and 'Explain the significance ...' were not underlined and probably ignored, so the candidate has gone off on entirely the wrong track.

Question 24 (b) (ii)

'Benzene is more stable because six carbon p-electrons are delocalised round the ring' is a simple way of gaining full credit. The mark for delocalisation of electrons was most commonly awarded. The stability mark was next most common, though it was often negated by contradictory statements like less energy required to break bonds.

(ii) Explain, in terms of the bonding in the benzene ring, why the enthalpy of hydrogenation is less exothermic than would be expected from a molecule with three double bonds.

(3)

Some of the energy is alweady used in the delocalization of electrons. The double bond Reeps on Shifting which makes it electron attracting in nature and thus more reactive so the enthalpy of hydrogenation is less exothermic.

While this gains credit for 'the delocalisation of electrons', it misses out on the stability mark due to the lack of understanding of energy which was quite a common problem. The molecule is more stable so it is less reactive, with a less negative enthalpy of hydrogenation. Energy is not used to delocalise electrons.

(ii) Explain, in terms of the bonding in the benzene ring, why the enthalpy of hydrogenation is less exothermic than would be expected from a molecule with three double bonds.

(3)

A molecular with 3 the bonds a value of -3 bold not -1 (for D)

change of hydrogenation in making benzene gives -205

less not -1. The ISS bis mot influence is the resource energy. This energy is the result of the increases steeling promoted by the debondied system of electrons in benzene. The ISS bis not is already stabilized by the debondied of the increases of the benzene molecule is already stabilized by the less than the benzene molecule is already stabilized by

This answer recognises the stability of benzene due to its delocalised electrons, but fails to mention which electrons are delocalised.

Question 24 (c)

Many careful candidates gained full credit here. Careless errors were the omission of charges in the equation for the formation of the nitronium ion, arrows drawn too loosely, and protons disappearing in the final step.

(c) The first steps in the preparation of an azo dye from benzene are shown below.

nitrobenzene

phenylamine

benzenediazonium cation

Give the mechanism for the reaction in step 1, including the equation for the formation of the electrophile.

(4)

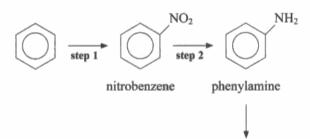

Equation for formation of electrophile

Mechanism

$$\frac{1}{\sqrt{NO_2}} + H_2SO_4$$

The only problem here is the full dashed line around the inside of the benzene ring in the intermediate state. It should of course go around all the atoms except the carbon with four bonds. (c) The first steps in the preparation of an azo dye from benzene are shown below.

benzenediazonium cation

Give the mechanism for the reaction in **step 1**, including the equation for the formation of the electrophile.

(4)

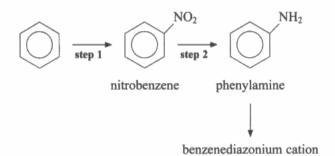

Equation for formation of electrophile

Mechanism

This is fine except that the arrow in the final step should go from the C-H bond into the benzene ring, rather than from the hydrogen.

(c) The first steps in the preparation of an azo dye from benzene are shown below.

Give the mechanism for the reaction in step 1, including the equation for the

(4)

Equation for formation of electrophile

formation of the electrophile.

Mechanism

This has several errors. First an oxygen is lost in the equation where an ${\rm HSO_3^-}$ ion is formed and a charge is missing from the ${\rm NO_2^+}$. Second the arrow in step 1 should go from the ring to the attacking group

Learn the detail of electrophilic aromatic substitution thoroughly.

Question 24 (d) (i)

It was necessary to consider both higher and lower temperatures. Then specific statements were needed.

(d) (i) Phenylamine is converted into the benzenediazonium cation using sodium nitrite and hydrochloric acid at a temperature between 0 °C and 10 °C.

Explain why the temperature must **not** be lower or higher than these limits if a good yield is to be obtained.

(2)

Any lower and the reaction will be to slow as there won't be enough

trinetic energy in the molecules. Any higher and secondary reactions will

start to take place forming different products

The first point is fine, the reaction would be too slow. The second is too vague.

(d) (i) Phenylamine is converted into the benzenediazonium cation using sodium nitrite and hydrochloric acid at a temperature between 0 °C and 10 °C.

Explain why the temperature must **not** be lower or higher than these limits if a good yield is to be obtained.

(2)

Or else, a phenol or an alcohol will be formed, which are

unwanted products A temperature of o°C to 10°C

should be maintained to prevent any unwanted products

to be formed thereby increasing the yield,

This does not make it clear when phenol forms. It does at higher temperatures than 10 °C.

(d) (i) Phenylamine is converted into the benzenediazonium cation using sodium nitrite and hydrochloric acid at a temperature between 0 °C and 10 °C.

Explain why the temperature must not be lower or higher than these limits if a good yield is to be obtained.

(2)

* Drasgodium compounds easily discoult / decompose

On tricreasing the temperature beyond 10° would result in no products because the products

would have dissociated decomposed.

Though a little convoluted, this response gains the second mark for the diazonium compound decomposing at higher temperatures. Unfortunately lower temperatures are not considered.

Always read the last line of a question particularly carefully.

Question 24 (d) (ii)

This was marked generously on charge position and on the benzene ring, where C-H bonds were not required.

The bonds have not been shown as requested in the question

(ii) Draw the structural formula of the benzenediazonium cation showing all the bonds and the charge.

(1)

Five bonds to a nitrogen never happen. Remove the hydrogen and this is fine.

Nitrogen forms three bonds, or four bonds if it is positively charged.

(ii) Draw the structural formula of the benzenediazonium cation showing all the bonds and the charge.

$$H - C \qquad C - C \qquad + C \qquad$$

A very good displayed formula but for one thing – the ring representing the delocalised bond is omitted.

There are normally four bonds made to each carbon.

Question 24 (d) (iii)

Many used phenol, though probably used 2-napthol in their class experiments. With phenol two benzene rings joined by N=N were needed, then an OH which could be in any position on a benzene ring.

(iii) Suggest how you could convert a sample of the benzenediazonium cation into an azo dye. Give the name of the other compound you would use and the skeletal formula of the azo dye you would obtain.
(3)

Name of the other compaund: phend

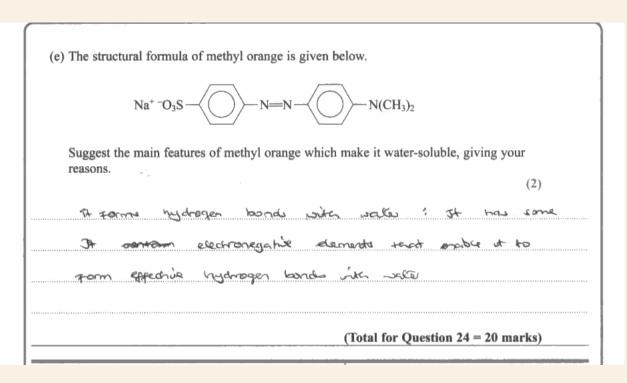

Structures involving alternating double and single bonds in the rings were fine, so this gains two marks. The phenol needs to be dissolved in sodium hydroxide.

Learn all details of chemicals used in experiments.

Question 24 (e)

The two marks and the question asking for the main features showed that two points were required. Many only gave one, usually the first about the potential of oxygen and nitrogen to hydrogen bond.

This answer needs to specify the actual elements in the compound which can hydrogen bond with water to gain the first mark. There is no mention of the interaction of the negative charge on the sulfonate group and the slightly positive hydrogen atoms in water. (e) The structural formula of methyl orange is given below. $Na^{+} \cdot O_{3}S \longrightarrow N = N \longrightarrow N(CH_{3})_{2}$ Suggest the main features of methyl orange which make it water-soluble, giving your reasons.

(2)

But the charges Lon Not and o₂S
Causes them to be hydrog hydrobool by water molecules when mixed with water.

The whole energy liberated is high enough bo

This gains the second mark but fails to mention hydrogen bonding with N or O in the compound for the first mark.

In questions on solubility consider all possibilities that help to make compounds soluble.

Paper Summary

Many good candidates were solid on the organic chemistry questions but found some of the physical chemistry questions more difficult, especially those involving electrode potentials. Most of the inorganic chemistry questions seemed to be answered correctly.

There were the usual issues with quality of written communication.

The word molecule was often used instead of attached group when writing about attached groups in molecular structures.

The terms molecule, atom and ion were also confused.

Hydration and hydrolysis were often confused, as were hydration and hydrogenation.
